# Some Approximations and Inequalities for Arc Tan and Ln

(Recibido el 13 de Diciembre, 1977)

## RESUMEN

La aplicación de la aproximación Padé a  $G = {}_2F_1(1, \alpha; \gamma; -k(z))$  conduce a mejores aproximaciones y desigualdades para  $G$  y también para la función  $F = {}_2F_1(1, a; c; -z)$ , las cuales son considerablemente mejores que aquellas que se obtienen directamente de  $F$ . Se ilustran los resultados para  $\arctan z$  y  $\ln(1+z)$ .

## SUMMARY

The application of the Padé approximations when applied to  $G = {}_2F_1(1, \alpha; \gamma; -k(z))$  leads to powerful approximations and inequalities for  $G$  and so also for  $F = {}_2F_1(1, a; c; -z)$ , which are considerably improved over those obtained directly from  $F$ . The results are illustrated for  $\arctan z$  and  $\ln(1+z)$ .

## 1. SUMMARY AND INTRODUCTION

In previous works [1, 2] we showed that the first sub-diagonal and main diagonal Padé approximations for

$F = {}_2F_1(1, a; c; -z)$  give lower and upper bounds, respectively for  $F$  when  $z > 0$  and suitable restrictions are placed on  $a$  and  $c$ . Now for certain values of  $a$  and  $c$ , there are available quadratic transformation formulas such that  $F$  is simply

related to the form  $G = {}_2F_1(1, \alpha; \gamma; -k(z))$  where  $k(z)$  is a function of  $z$ . The convergence properties of  $G$  are vastly

superior to those for  $F$  since  $|k(z)| \leq |z|$ ,  $z$  suitably restricted. Thus application of the Padé approximations noted above when applied to  $G$  leads to powerful approximations and inequalities for  $G$  and so also for  $F$  which are noticeably improved over those obtained directly from  $F$ . The results are illustrated for  $\arctan z$  and  $\ln(1+z)$ .

## 2. APPROXIMATIONS AND INEQUALITIES FOR

$${}_2F_1(1, a; c; -z)$$

Consider

$$F(z) = {}_2F_1(1, a; c; -z). \quad (1)$$

Let

$$F(z) = [A_n(z)/B_n(z)] + U_n(z), \quad (2)$$

where  $[A_n(z)/B_n(z)]$  is the first subdiagonal Padé approximation for  $F(z)$  and  $U_n(z)$  is the error. Again, let

$$F(z) = [G_n(z)/D_n(z)] + V_n(z), \quad (3)$$

where  $\{C_n(z)/D_n(z)\}$  is the main diagonal Padé approximation for  $F(z)$  and  $V_n(z)$  is the error. Numerous details concerning the polynomials in these Padé approximations and the errors are detailed in my volumes [1, 2]. For the most part these data will not be repeated here. For our present purposes, we need only the inequality

$$\{A_n(z)/B_n(z)\} < F(z) < \{C_n(z)/D_n(z)\},$$

$$z > 0, c \geq 1, c > a > 0, \quad (4)$$

with equality if  $z = 0$  or  $a = 0$  except that if  $z = 0$ , exclude the left hand inequality unless  $n > 0$ .

Other conditions for the validity of (4) as is or of (4) with inequality signs reversed are given in the sources cited.

In particular, we have

$$B_0(z) = C_0(z) = D_0(z) = 1, A_0(z) = 0,$$

$$A_1(z) = 1, B_1(z) = 1 + az/c$$

$$A_2(z) = 1 + \left(\frac{2(a+1)}{c+2} - \frac{a}{c}\right)z,$$

$$B_2(z) = 1 + \frac{2(a+1)z}{c+2} + \frac{(a+1)az^2}{(c+2)(c+1)},$$

$$C_1(z) = 1 + \frac{(c-a)z}{c(c+1)}, D_1(z) = 1 + \frac{(a+1)z}{(c+1)},$$

$$C_2(z) = 1 + \left(\frac{2(a+2)}{c+3} - \frac{a}{c}\right)z + \left(\frac{(a+1)(a+2)}{(a+2)(a+3)} - \frac{2a(a+2)}{c(c+3)} + \frac{a(a+1)}{c(c+1)}\right)z^2$$

$$D_2(z) = 1 + \frac{2(a+2)z}{(c+3)} + \frac{(a+2)(a+1)z^2}{(c+3)(c+2)},$$

and further approximants can be found after the manner in the cited references.

### 3. APPROXIMATIONS AND INEQUALITIES FOR ARC TAN Z

We first derive a quadratic transformation formula for

$$\text{arc tan } z = z {}_2F_1\left(\frac{1}{2}; 3/2; -z^2\right). \quad (6)$$

Consider [1, Vol. 1, p. 92, Eq. (1)] or [2, p. 270, Eq. (1)] with

$$z \text{ replaced by } -\left(\frac{W-1}{z}\right) \text{ where } W = (1+z^2)^{\frac{1}{2}}. \quad (7)$$

Then

$${}_2F_1\left(a, a + \frac{1}{2}; c; -z^2\right) = \left(\frac{2}{1+W}\right)^{2a} {}_2F_1\left(2a, 2a - c + 1; c; \frac{1-W}{1+W}\right) \quad (8)$$

$$= W^{-2a} {}_2F_1\left(2a, 2c - 2a - 1; c; \frac{W-1}{2W}\right)$$

in virtue of a Kummer transformation formula. Now put  $a = \frac{1}{2}$ . The  ${}_2F_1$  on the right can be expressed as 1 plus another  ${}_2F_1$  to which we apply a Kummer transformation formula. We so obtain the desired form

$${}_2F_1\left(1, \frac{1}{2}; c; -z^2\right) = \frac{1}{W} + \frac{(W-1)^2(c-1)}{z^2 W c}$$

$${}_2F_1\left(1, 2-c; c+1; -\left(\frac{W-1}{z}\right)^2\right),$$

$$|\arg(1+z^2)| < \pi, z^2 \neq -1, \quad (9)$$

which with  $c = 3/2$  gives  $z^{-1} \text{arc tan } z$ . Note that  $\{(w-1)/z\}$  vanishes if  $z \rightarrow 0$  and increases monotonically to 1 as  $z \rightarrow \infty$ . The Padé approximations for the  ${}_2F_1$  on the right hand side of (9) lead to powerful approximations for the  ${}_2F_1$  on the left and these approximations are vastly superior to the corresponding Padé approximations for the  ${}_2F_1$  on the left hand side of (9). Application of the results in Section 2 to (9) with  $c = 3/2$  yields the following approximations and inequalities for arc tan z.

$$z^{-1} L_n \leq z^{-1} \arctan z \leq z^{-1} R_n, z \geq 0, \quad (10)$$

$$L_1 = \frac{z}{w} + \frac{10v^2 z}{3w(v^2 + 5)},$$

$$R_1 = \frac{z}{w} + \frac{2v^2 z(8v^2 + 35)}{3w(15v^2 + 35)}, \quad (11)$$

$$v = \frac{w-1}{z} = \frac{z}{w+1}, w = (1+z^2) \frac{1}{2}, \quad (12)$$

$$L_2 = \frac{z}{w} + \frac{14v^2 z(7v^2 + 15)}{15w(v^4 + 14v^2 + 21)},$$

$$R_2 = \frac{z}{w} + \frac{2v^2 z(64v^4 + 819v^2 + 1155)}{105w(5v^4 + 30v^2 + 33)} \quad (13)$$

The inequalities become exact as  $z \rightarrow 0$ . If  $z = 1$ , we find

$$L_1 = \frac{41(2)^{\frac{1}{2}} - 25}{42} = 0.78530372 < \pi/4$$

$$= 0.7853981634$$

$$< R_1 = \frac{811(2)^{\frac{1}{2}} - 605}{690} = 0.78540174,$$

$$L_2 = \frac{325(2)^{\frac{1}{2}} - 224}{300} = 0.7853980259 < \pi/4$$

$$< R_2 = \frac{53301(2)^{\frac{1}{2}} - 38104}{47460} = 0.7853981687.$$

If  $z \rightarrow +\infty, z/w \rightarrow 1$  and  $v \rightarrow 1$ . So

$$L_1 = 14/9 = 1.55556 < \pi/2$$

$$= 1.57079633 < 118/75 = 1.57333,$$

$$L_2 = 212/135 = 1.57037037 < \pi/2 < R_2$$

$$= \frac{2804}{1785} = 1.57086835.$$

#### 4. APPROXIMATIONS AND INEQUALITIES FOR $\ln(1+z)$

We first get a quadratic transformation formula for

$$\ln(1+z) = z {}_2F_1(1, 1; 2; -z). \quad (14)$$

Consider [1, Vol. 1, p. 93, Eq. (8)] or [2, p. 271, Eq. (8)] with  $a = 1$  and  $z$  replaced by  $-z/2$ . Apply a Kummer transformation formula to the  ${}_2F_1$  on the right hand side of the resulting equation, and so obtain

$${}_2F_1(1, b; 2; -z) = \frac{(z+2)}{(2z+2)^{\frac{1}{2}}(b+1)}$$

$${}_2F_1\left(\frac{b+1}{2}, \frac{3-b}{2}; \frac{3}{2}; \frac{z^2}{4(z+1)}\right),$$

$$|\arg(1+z)| < \pi, \quad \left| \arg \frac{(z+2)^2}{(z+1)} \right| < \pi, \quad (15)$$

and with  $b = 1$ , we have a formula for  $z^{-1} \ln(1+z)$ . Application of the results in Section 2 yields the following approximations and inequalities.

$$L_n \leq \ln(1+z) \leq R_n, z > 0, \quad (16)$$

$$L_1 = \frac{3z(z+2)}{2(z+1)(2y+3)}, R_1 = \frac{z(z+2)(2y+15)}{6(z+1)(4y+5)}, \quad (17)$$

$$y = z^2/4(z+1), \quad (18)$$

$$L_2 = \frac{5z(z+2)(10y+21)}{6(z+1)(8y^2+40y+35)},$$

$$R_2 = \frac{z(z+2)(8y^2+210y+315)}{30(z+1)(8y^2+28y+21)} \quad (19)$$

These inequalities become exact as  $z \rightarrow 0$ .

In illustration, with  $z = 2$ , we have

$$L_1 = \frac{12}{11} = 1.09091 < \ln 3 = 1.098612289 <$$

$$R_1 = \frac{188}{171} = 1.09941$$

$$L_2 = \frac{1460}{1329} = 1.098570354 < \ln 3 < R_2$$

$$= \frac{13892}{12645} = 1.098616054.$$

We now get another quadratic transformation formula for the logarithm which is even more powerful than (15). Consider [1, Vol. 1, p. 93, Eq. (7)] or [2, p. 271, Eq. (7)] with  $z$  replaced by  $-z$ . Apply a Kummer transformation formula to the right hand side of this equation. Then

$${}_2F_1(a, b; 2a; -z) = u^{-b} {}_2F_1\left(b, 2a-b; a + \frac{1}{2}; -\frac{(1-u)^2}{4u}\right),$$

$$u = (1+z)^{\frac{1}{2}}, \quad |\arg(1+z)| < \pi,$$

$$|\arg(1+u)^2/u| < \pi, \quad (20)$$

and if  $a = b = 1$ , we have an expression for  $z^{-1} \ln(1+z)$ . Application of the results in Section 2 yields the following approximations and inequalities.

$$L_n \leq \ln(1+z) \leq R_n, z > 0, \quad (21)$$

$$L_1 = \frac{6z}{u^2 + 4u + 1}, R_1 = \frac{z(u^2 + 28u + 1)}{6u(u^2 + 3u + 1)}, \quad (22)$$

$$L_2 = \frac{5z(5u^2 + 32u + 5)}{3(u^4 + 16u^3 + 36u^2 + 16u + 1)},$$

$$R_2 = \frac{z(u^4 + 101u^3 + 426u^2 + 101u + 1)}{15u(u^4 + 10u^3 + 20u^2 + 10u + 1)} \quad (23)$$

These inequalities become exact as  $z \rightarrow 0$ .

In illustration, with  $z = 2$ , we get

$$L_1 = \frac{3(3^{\frac{1}{2}} - 1)}{2} = 1.09807\ 6211 <$$

$$\ln 3 = 1.09861\ 2289$$

$$< R_1 = \frac{4(59(3)^{\frac{1}{2}} - 75)}{99} = 1.09862\ 6168,$$

$$L_2 = \frac{20(312(3)^{\frac{1}{2}} - 473)}{1227}$$

$$= 1.09861\ 2094 < \ln 3$$

$$< R_2 = \frac{4(1042(3)^{\frac{1}{2}} - 1743)}{225} = 1.09861\ 2293 :$$

Shafer [3] initiated the technique of quadratic approximation and in illustration shows that

$$\arctan x = \frac{8x}{3 + (25 + 80x^2/3)^{\frac{1}{2}}} + \varepsilon(x), x > 0. \quad (24)$$

It can be proved that  $\varepsilon'(x) > 0$  for  $x > 0$  and since  $\varepsilon(x) = 0$  for  $x = 0$ , (24) gives a left hand inequality for  $\arctan x$  when  $x \geq 0$ .  $\varepsilon(x)$  increases monotonically for  $0 \leq x < \infty$ , and  $\varepsilon(x) \rightarrow 1.5492$  as  $x \rightarrow \infty$ . For a comparable situation note that when  $x \rightarrow \infty$ , then from (11),  $L_1 \rightarrow 1.5556$ . Since the true value is  $\pi/2$ , we see that the left hand inequality (10) with  $n = 1$  is superior.
